Matching in graphs

Daniel Rosenberg & Michael Trushkin

Ariel University

1. Tutte's Theorem

For bipartite graphs $G := (A \cup B, E)$

G has a perfect
matching

$\iff$

$|A| = |B|$
and A satisfies the
Hall-Condition

Question 1 what if G is not bipartite?

Goal : Find a necessary & sufficient condition for the emergence of perfect matchings in *general* graphs.

- G graph and $S \subseteq V(G)$
- $G - S :=$ the graph obtained by removing the vertices S in G .
 - $G - S$ is a sub-graph of G .

- We can break the graph into the set S and the connected components of $G - S$.
- **No edges between connected components**

No perfect matching, there is 4 components, with odd number of vertices.

But S can only “give” at most 3 vertices.

- Let G be a graph.
- $\text{Co}(G - S) :=$ number of odd components in $G - S$.
- If $\exists S \subseteq V(G)$ s.t. $\text{Co}(G - S) > |S|$
 - G has no perfect matching

- $\text{Co}(G - S) :=$ number of odd components in $G - S$.

Theorem 1 (Tutte's) Let G be a graph. Then,

$$G \text{ has a p.m.} \iff \underbrace{|\text{Co}(G - S)| \leq |S|, \forall S \subseteq V(G)}_{\text{Tutte's Condition}}$$

We already proven $\implies$

Remark

A graph satisfying

$$|\text{Co}(G - S)| \leq |S|, \forall S \subseteq A.$$

Is said to satisfy the Tutte's condition.

2. General Proof Idea

- Suppose the claim is false.
 - G satisfies Tutte's condition and has no perfect matching.
- Let G be “edge-maximal” example of such a graph.
 - **What does G look like? What are the properties of such a graph?**

Observation 2

- G satisfying the tutte condition
- e an edge not in G

Then, $G' := G + e$ also satisfies the tutte's condition.

Proof. Fix $S \subseteq V(G)$ and show that for any edge $\text{Co}(G - S + e) \leq |S|$.

- if e is an edge that resides inside any component. inside of S , or between S and any component.
 - Then, there is no change $\text{Co}(G - S + e) = \text{Co}(G - S) \leq |S|$.

- e is an edge with one end inside an even component:
 - If its between two even components. Then, we get one big even components instead of two even components so that $\text{Co}(G - S + e) = \text{Co}(G - S) \leq |S|$.
 - If its between even and odd components. Then, we get one big odd components instead of the previous odd and even components so that $\text{Co}(G - S + e) = \text{Co}(G - S) \leq |S|$.

- If e is an edge with both ends in different odd components:
 - Then, we get one even component instead of the two odd components so that $\text{Co}(G - S + e) = \text{Co}(G - S) - 2 \leq |S| - 2 \leq |S|$.

Observation 3

- G graph, satisfying the Tutte's condition

Then, $v(G) = n$ is even.

Tutte's Condition:

$$|\text{Co}(G - S)| \leq |S|, \forall S \subseteq A.$$

Proof. Set $S = \emptyset$.

- $|\text{Co}(G - S)| = |\text{Co}(G)| \leq |S| = 0$
 - Every connect component of G must have an even number of vertices.

□

3. Construction edge maximal counter example

Theorem 2 (Tutte's) Let G be a graph. Then,

$$G \text{ has a p.m.} \iff \underbrace{|\text{Co}(G - S)| \leq |S|, \forall S \subseteq V(G)}_{\text{Tutte's Condition}}$$

- Assume that $\exists G$ satisfying the Tutte's condition without a p.m.
 - If $\exists e \notin E(G)$ s.t. $G + e$ still has no p.m.
 - Set $G := G + e$.

We obtain a graph G with the following properties:

1. G satisfies the Tutte's condition
2. G has no perfect matching
3. $\forall e \notin E(G) : G + e$ has a perfect matching.

G is called an edge maximal counter example!

A graph satisfying (2,3) is an **SNF graph!**

**SNF graphs do not
satisfy Tutte's condition**

4. SNF graphs

Definition 2 (SNF Graph's) A graph G is called **Saturated non-fractorisable** graph if it satisfies:

1. G has no perfect matching
2. $G + e$ has a perfect matching $\forall e \notin E(G)$

Remark

If $v(G) = n$ is odd.
Then, $G = K_n$.

How do even SNF graph look like? **Proof is left for the TA session.**

- $\exists S \in V(G)$ and $k \in \mathbb{N}$ s.t. $S = K_k$.
 - $G - S$ consist of $k + 2$ odd cliques.

This means that any SNF graph by construction doesnt sayfies the Tutte's condition! In particular setting S to the K_k we have $\text{Co}(G - S) = k + 2 > k = |S|$.

In the example above, $S = K_3$ and there is 5 odd components in $G - S$.

Conclusion.

- If G is an even sized **SNF graph**.
 - $\exists S \in V(G)$ s.t. $\text{Co}(G - S) = |S| + 2 > |S|$. $\implies G$ doesn't satisfy the Tutte's condition!

Back to the proof: Let G be a counter example i.e.

- G satisfies the Tutte's condition & G has no perfect matching

$\implies$ Construct an edge maximal counter example from G called G^* . $\implies G^*$ is an **SNF graph** & G^* satisfies the Tutte's condition. $\implies$ Any **SNF graph** doesn't satisfy Tutte's so it's a contradiction. $\implies G^*$ cannot exist $\implies G$ cannot exist. $\implies$ If G satisfies the Tutte's condition then G must have a perfect matching!
